

Handling missing data

Emily Fox & Carlos Guestrin
Machine Learning Specialization
University of Washington

Decision tree review

So far: data always completely observed

Credit	Term	Income	y
excellent	3 yrs	high	safe
fair	5 yrs	low	risky
fair	3 yrs	high	safe
poor	5 yrs	high	risky
excellent	3 yrs	low	risky
fair	5 yrs	low	safe
poor	3 yrs	high	risky
poor	5 yrs	low	safe
fair	3 yrs	high	safe

Known x and y
values for all
data points

Missing data

Credit	Term	Income	y
excellent	3 yrs	high	safe
fair	?	low	risky
fair	3 yrs	high	safe
poor	5 yrs	high	risky
excellent	3 yrs	low	risky
fair	5 yrs	high	safe
poor	?	high	risky
poor	5 yrs	low	safe
fair	?	high	safe

Loan application
may be
3 or 5 years

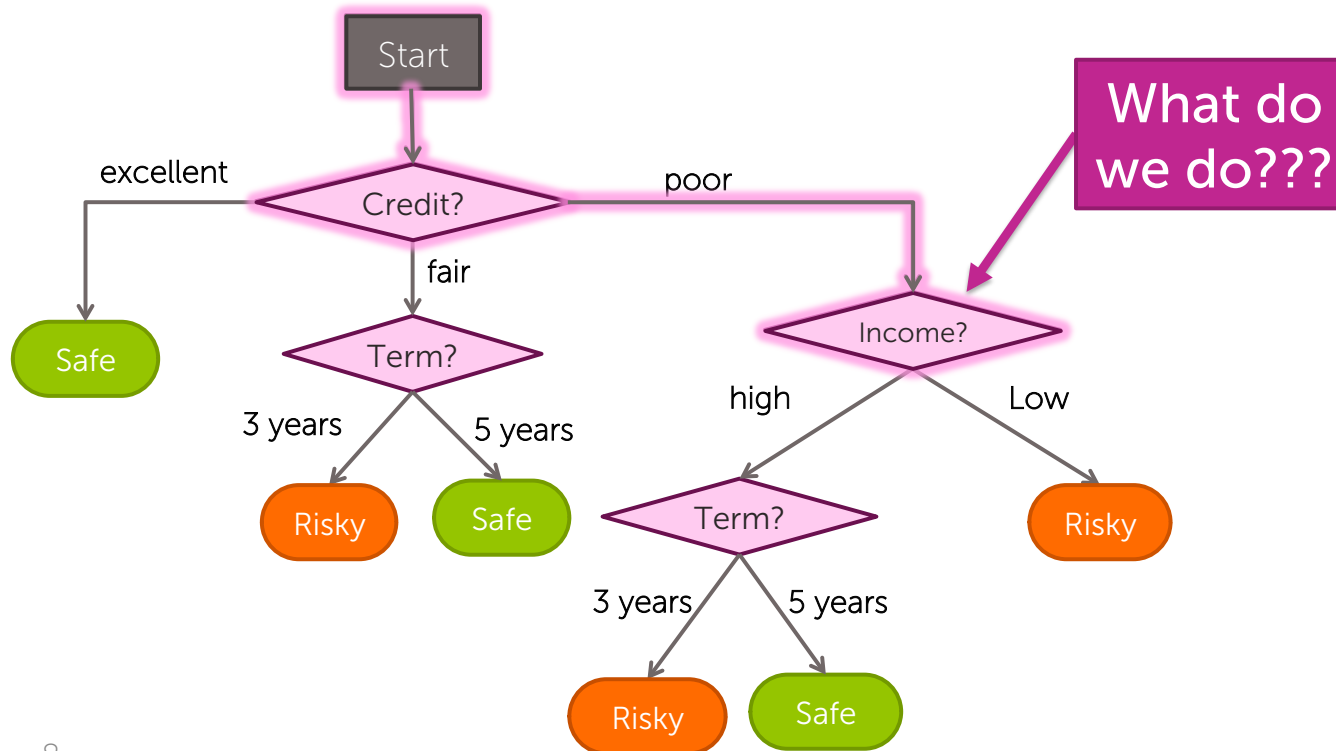

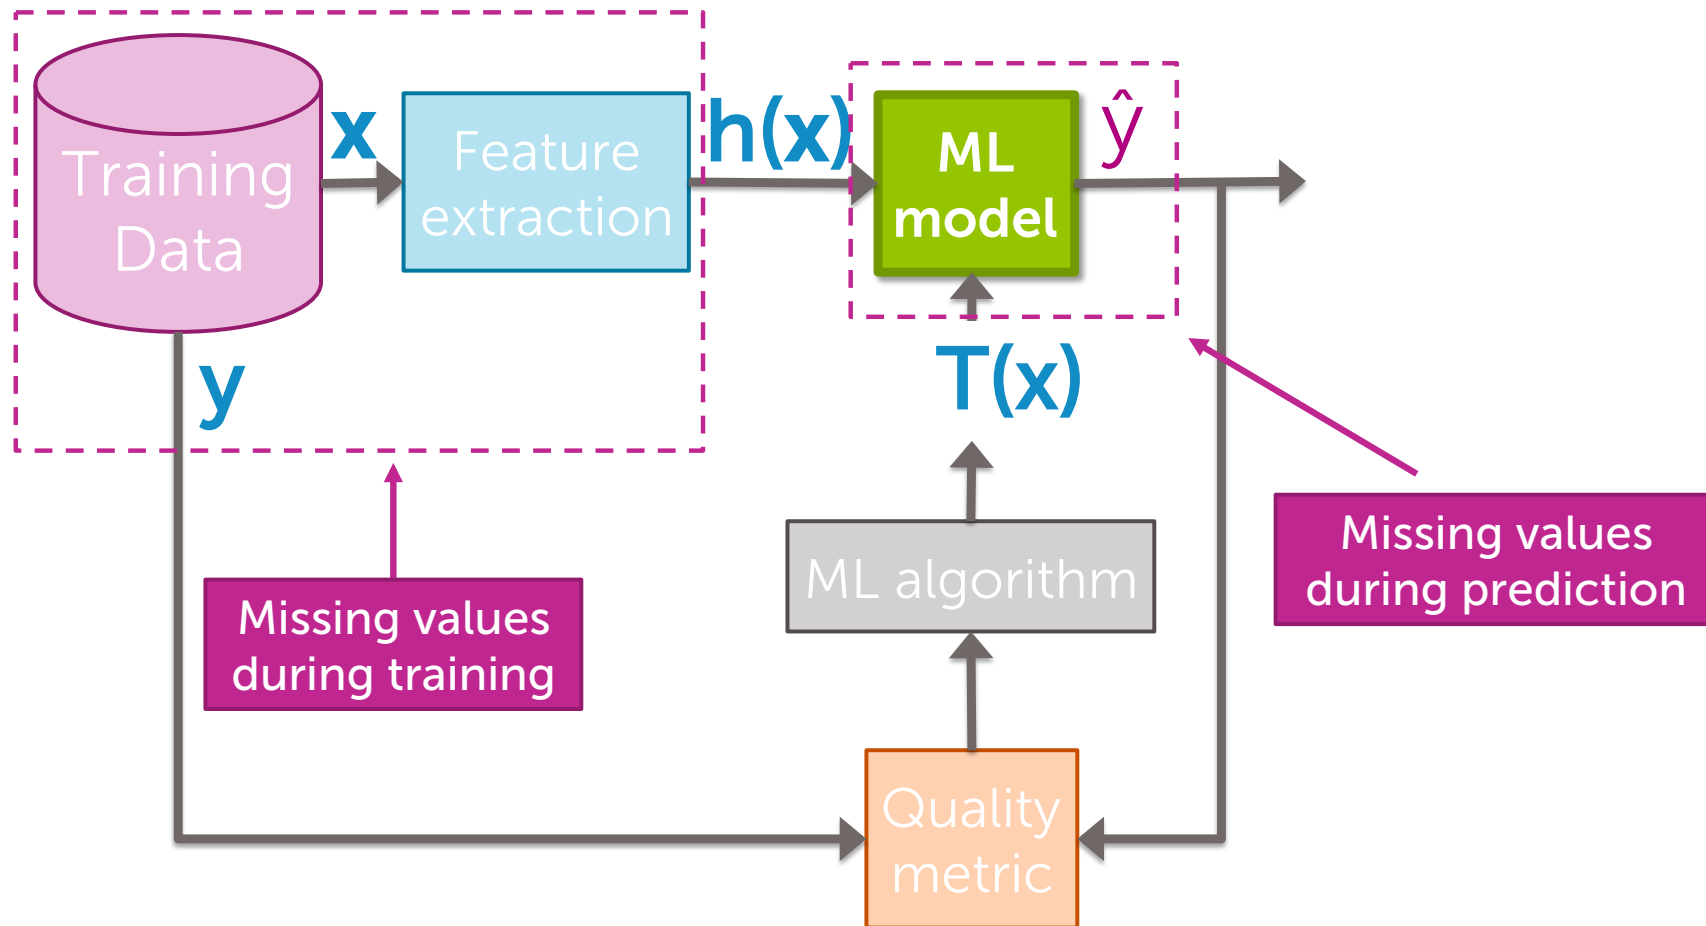

Missing values impact training and predictions

1. **Training data:** Contains “unknown” values
2. **Predictions:** Input at prediction time contains “unknown” values

Missing values during prediction

$\mathbf{x}_i = (\text{Credit} = \text{poor}, \text{Income} = ?, \text{Term} = 5 \text{ years})$

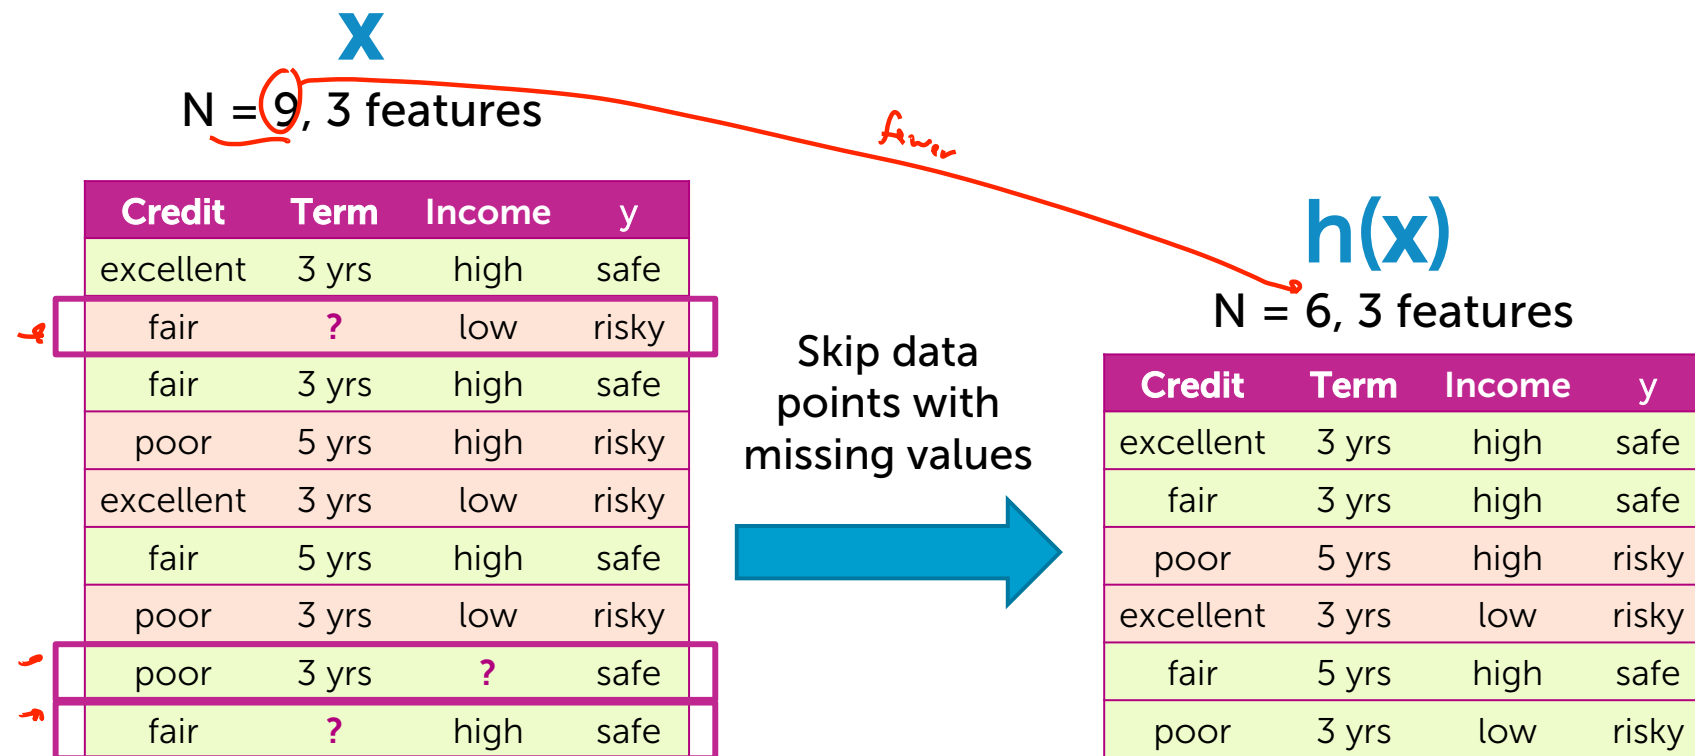

Handling missing data

Strategy 1: Purification by skipping

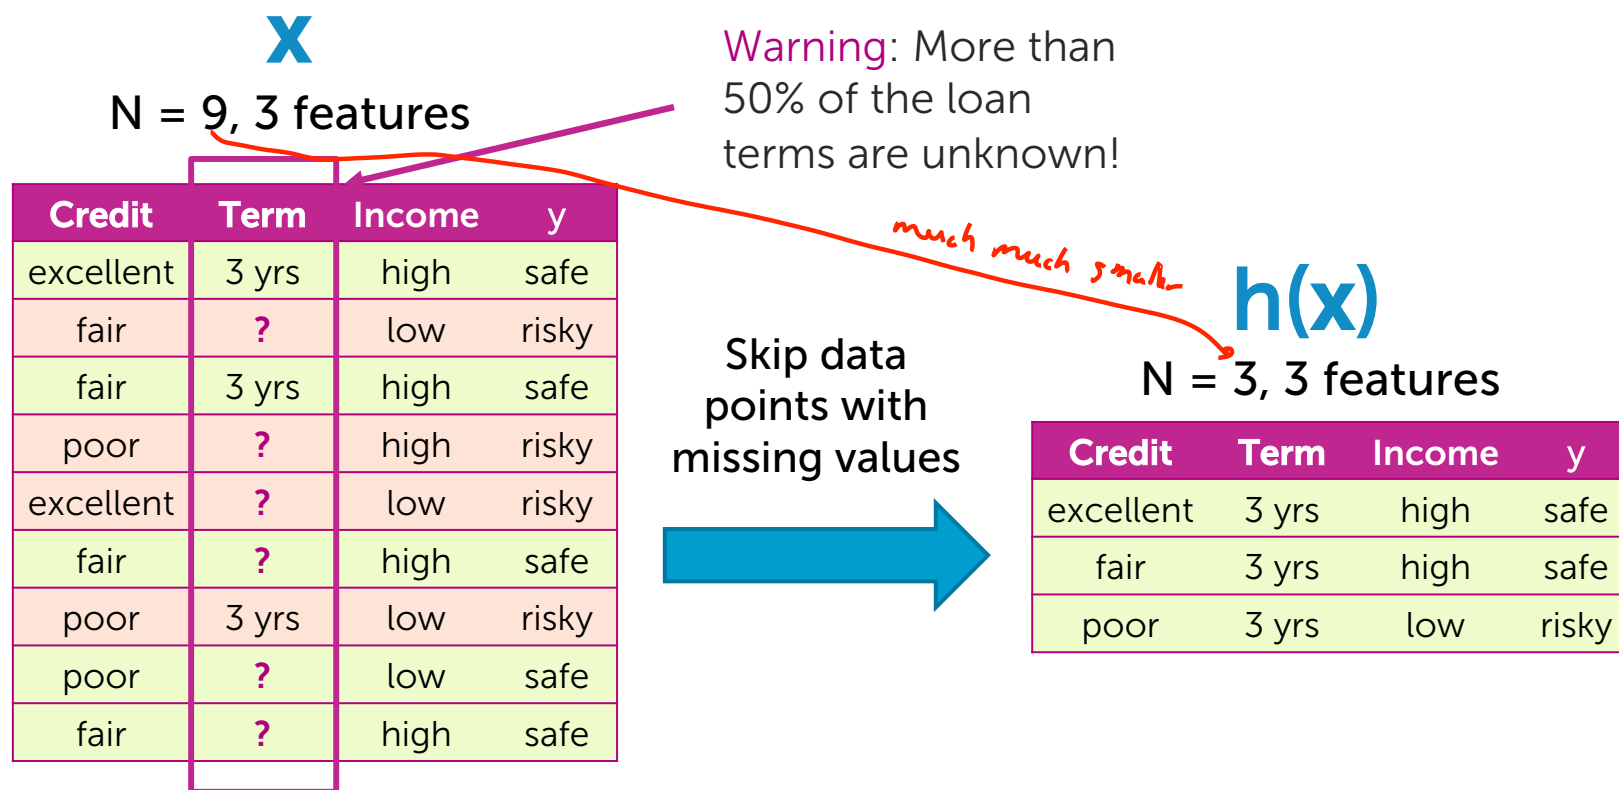

Idea 1: Purification by skipping/removing

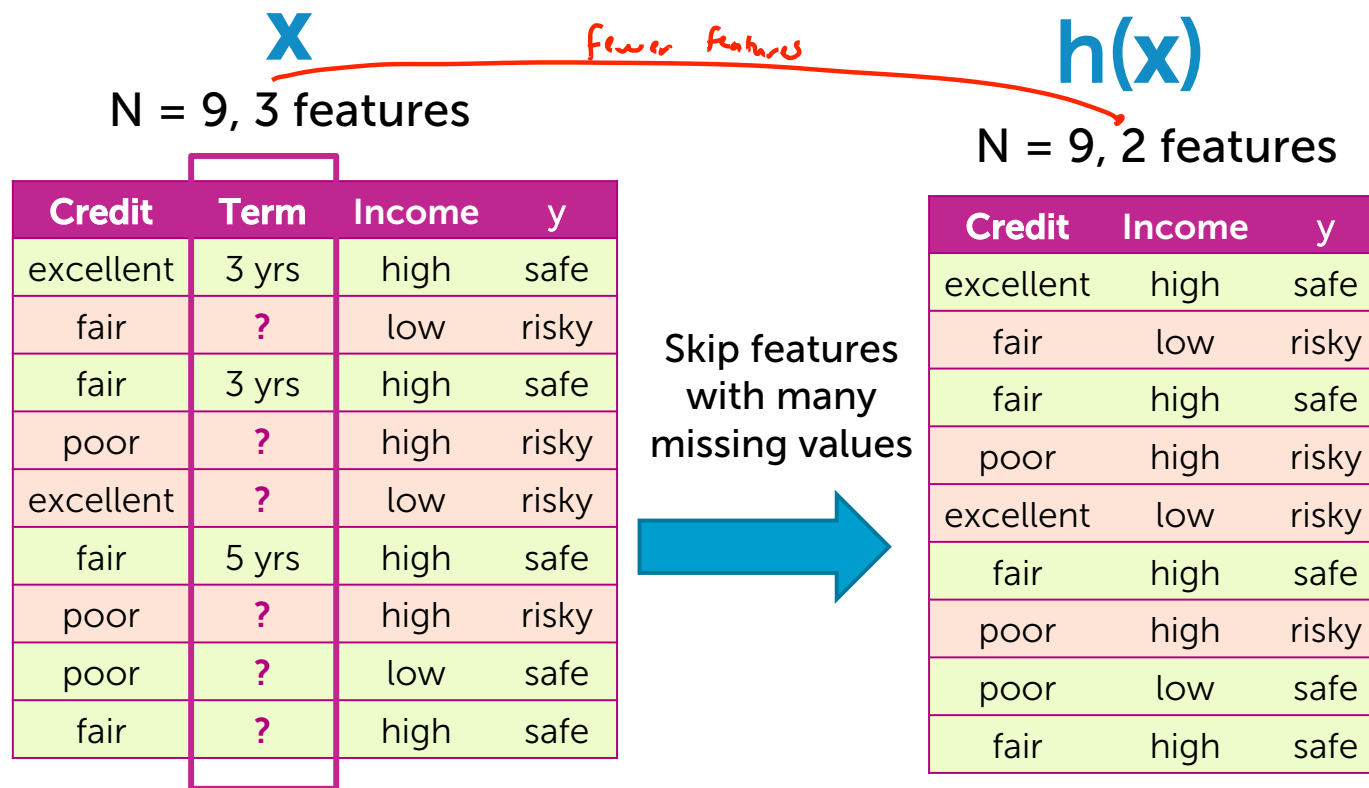

Idea 1: Skip data points with missing values

The challenge with Idea 1

Idea 2: Skip features with missing values

Missing value skipping: Ideas 1 & 2

Idea 1: Skip data points where any feature contains a missing value

- Make sure only a few data points are skipped

Idea 2: Skip an entire feature if it's missing for many data points

- Make sure only a few features are skipped

Missing value skipping: Pros and Cons

Pros

- Easy to understand and implement
- Can be applied to any model (decision trees, logistic regression, linear regression,...)

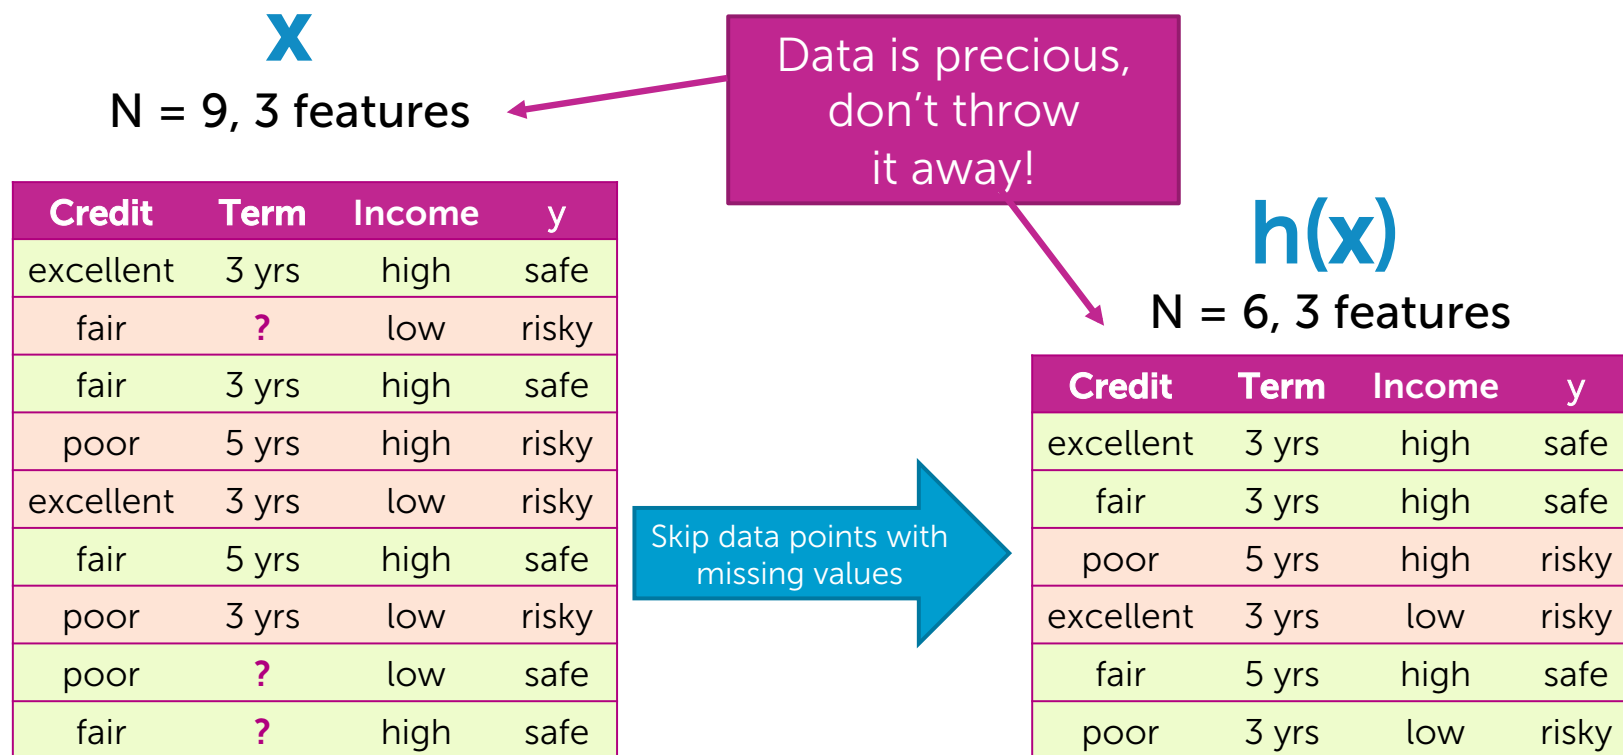

Cons

- Removing data points and features may remove important information from data
- Unclear when it's better to remove data points versus features
- Doesn't help if data is missing at prediction time

Handling missing data

Strategy 2: Prification by imputing

Main drawback of skipping strategy

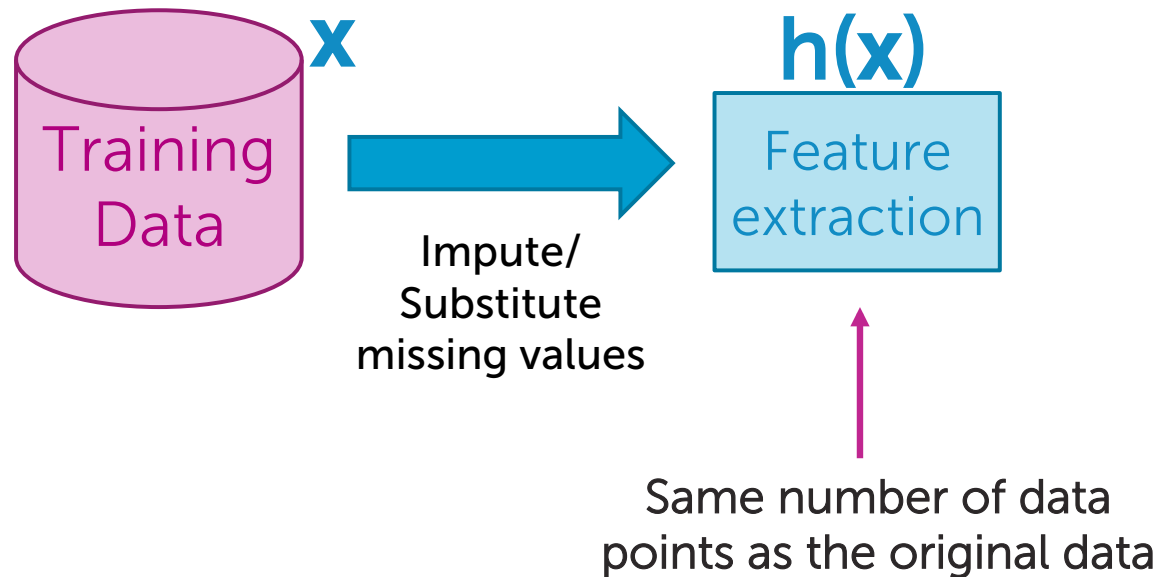

Can we keep all the data?

credit	term	income	y
excellent	3 yrs	high	safe
fair	?	low	risky
fair	3 yrs	high	safe
poor	5 yrs	high	risky
excellent	3 yrs	low	risky
fair	5 yrs	high	safe
poor	3 yrs	high	risky
poor	?	low	safe
fair	?	high	safe

Use other data points
in \mathbf{x} to "guess" the "?"

Idea 2: Purification by imputing

Idea 2: Imputation/Substitution

N = 9, 3 features

Credit	Term	Income	y
excellent	3 yrs	high	safe
fair	?	low	risky
fair	3 yrs	high	safe
poor	5 yrs	high	risky
excellent	3 yrs	low	risky
fair	5 yrs	high	safe
poor	3 yrs	high	risky
poor	?	low	safe
fair	?	high	safe

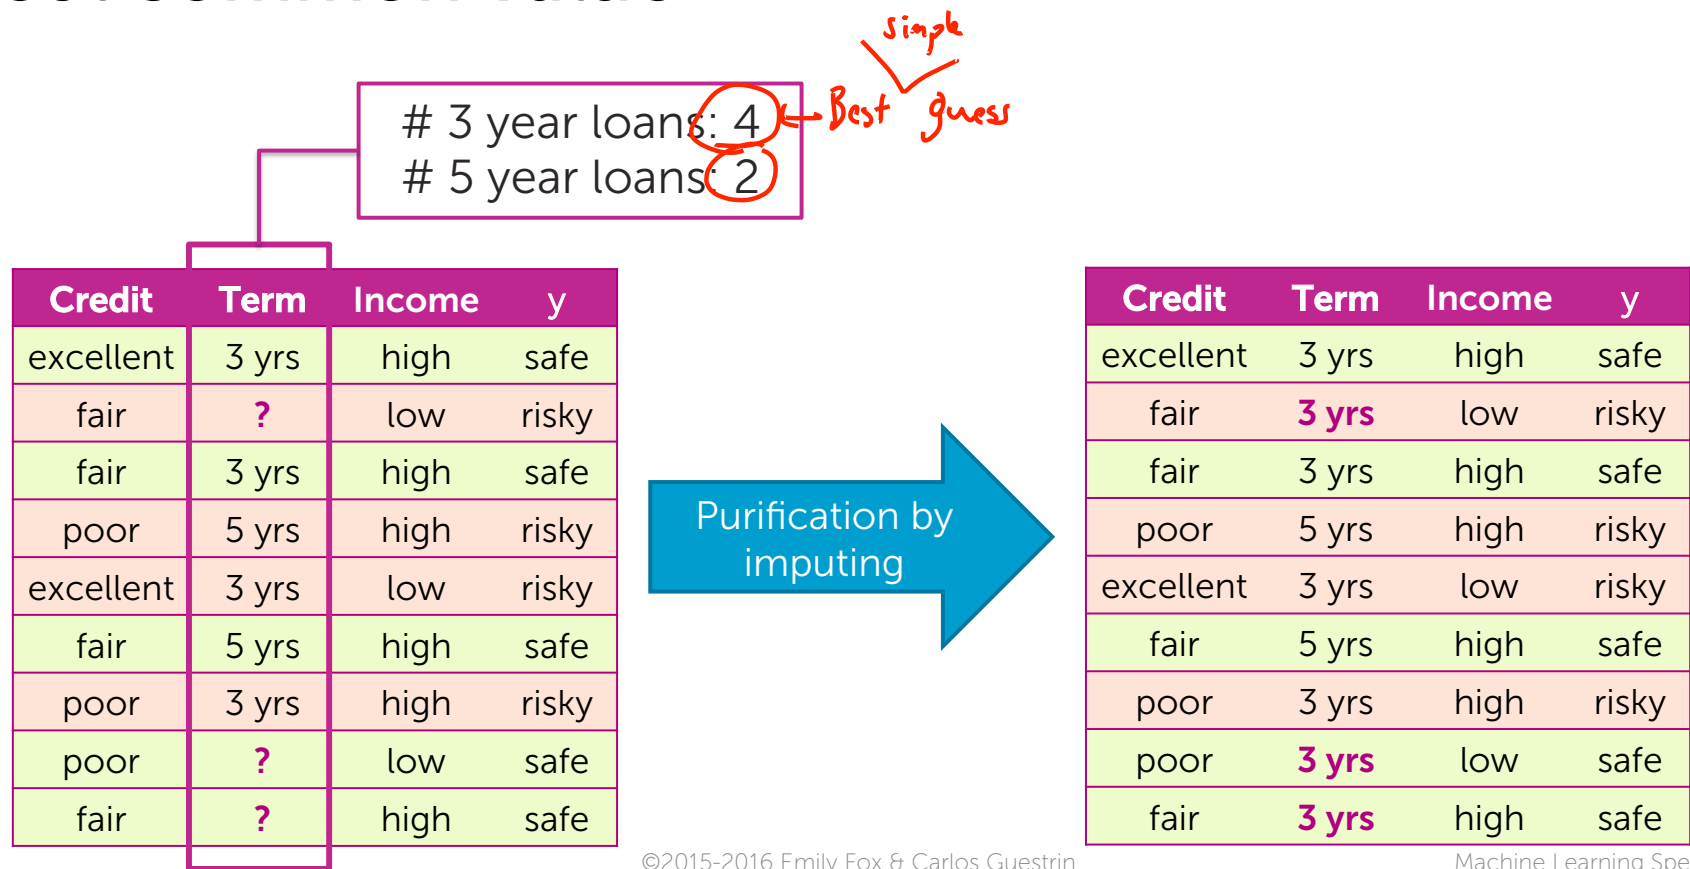

Fill in each missing value with a calculated guess

N = 9, 3 features

Credit	Term	Income	y
excellent	3 yrs	high	safe
fair	3 yrs	low	risky
fair	3 yrs	high	safe
poor	5 yrs	high	risky
excellent	3 yrs	low	risky
fair	5 yrs	high	safe
poor	3 yrs	high	risky
poor	3 yrs	low	safe
fair	3 yrs	high	safe

Example: Replace ? with most common value

Common (simple) rules for purification by imputation

Credit	Term	Income	y
excellent	3 yrs	high	safe
fair	?	low	risky
fair	3 yrs	high	safe
poor	5 yrs	high	risky
excellent	3 yrs	low	risky
fair	5 yrs	high	safe
poor	3 yrs	high	risky
poor	?	low	safe
fair	?	high	safe

Impute each feature with missing values:

1. Categorical features use mode: Most popular value (mode) of non-missing x_i
2. Numerical features use average or median: Average or median value of non-missing x_i

Many advanced methods exist,
e.g., expectation-maximization (EM) algorithm

Missing value imputation: Pros and Cons

Pros

- Easy to understand and implement
- Can be applied to any model
(decision trees, logistic regression, linear regression,...)
- Can be used at prediction time: use same imputation rules

Cons

- May result in systematic errors

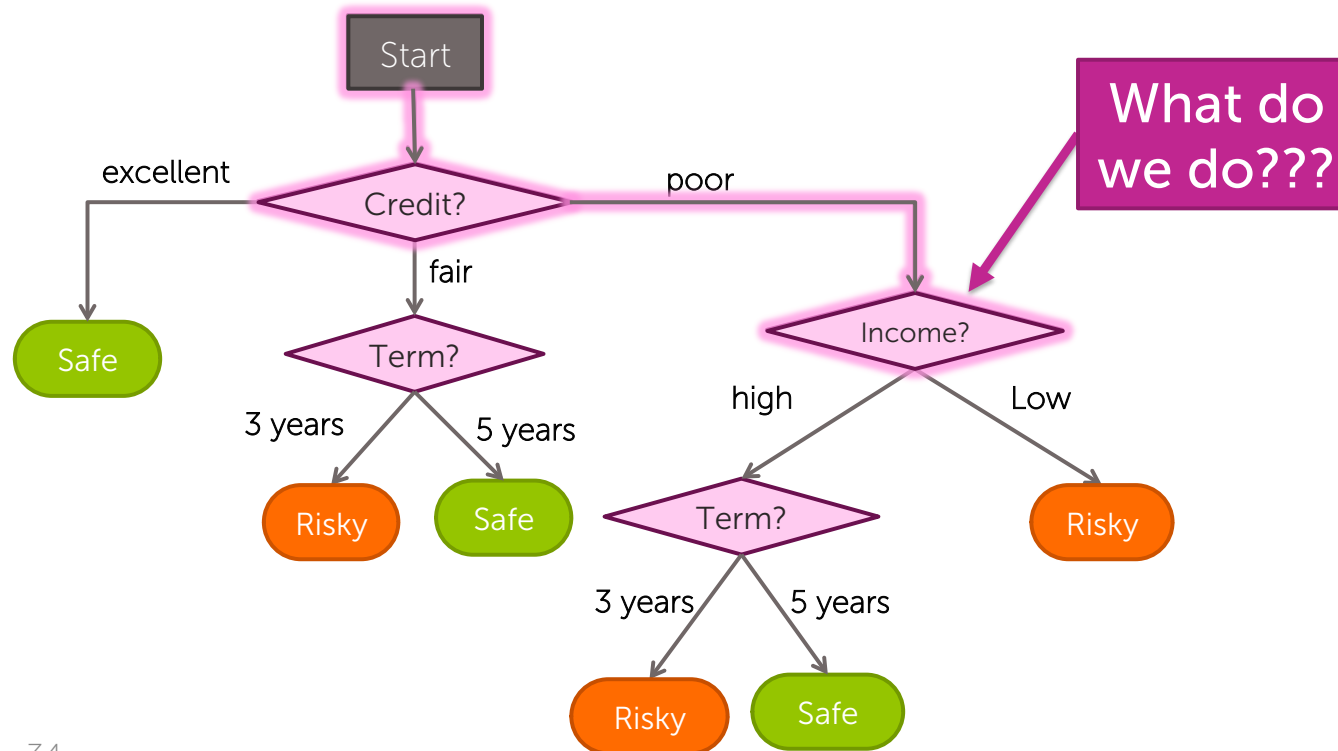

Example: Feature “age” missing in all banks in Washington by state law

Handling missing data

*Strategy 3: Adapt learning algorithm
to be robust to missing values*

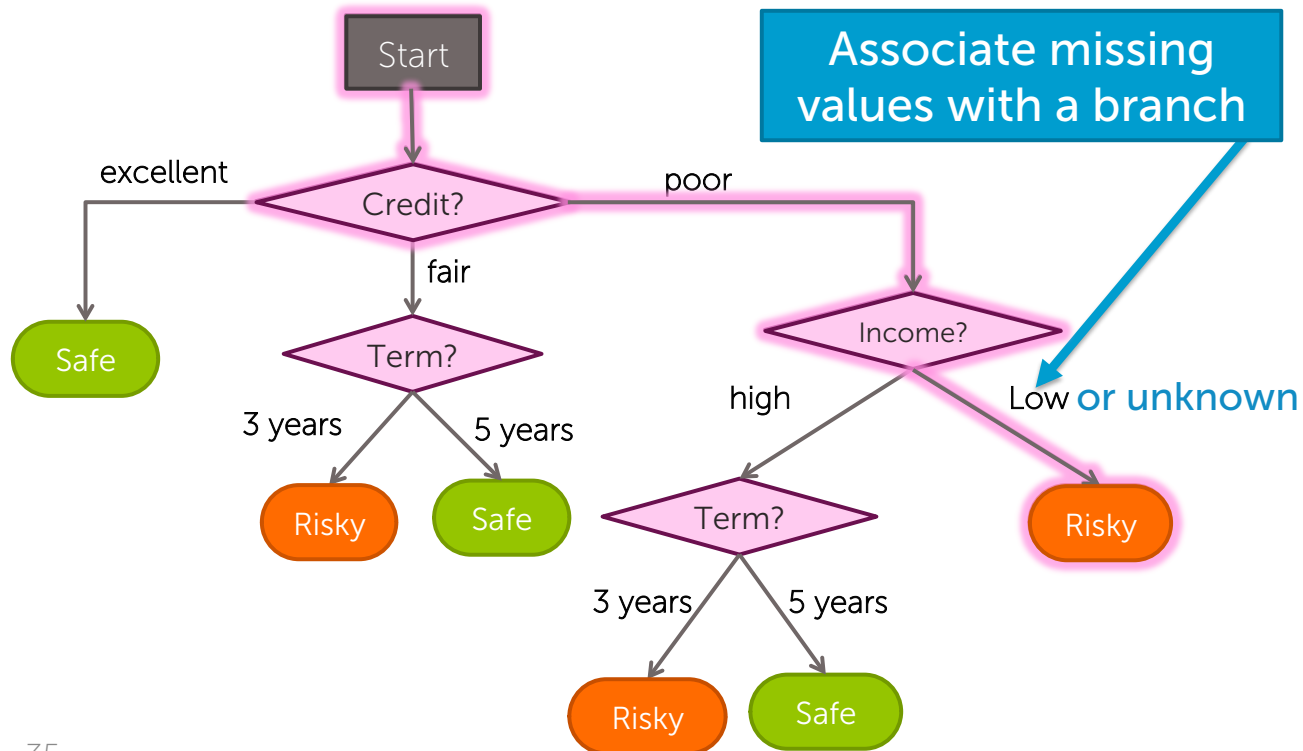

Missing values during prediction: *revisited*

$\mathbf{x}_i = (\text{Credit} = \text{poor}, \text{Income} = ?, \text{Term} = 5 \text{ years})$

Add missing values to the tree definition

$\mathbf{x}_i = (\text{Credit} = \text{poor}, \text{Income} = ?, \text{Term} = 5 \text{ years})$

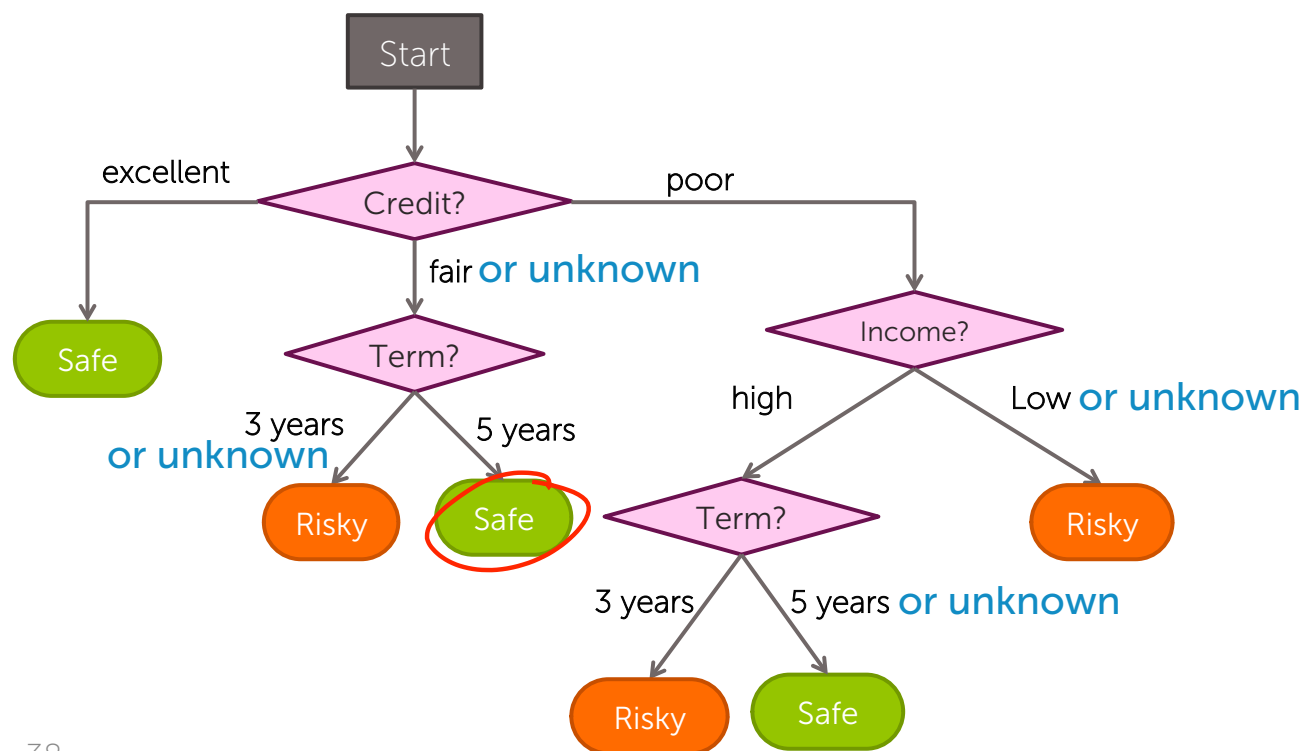

Add missing value choice to every decision node

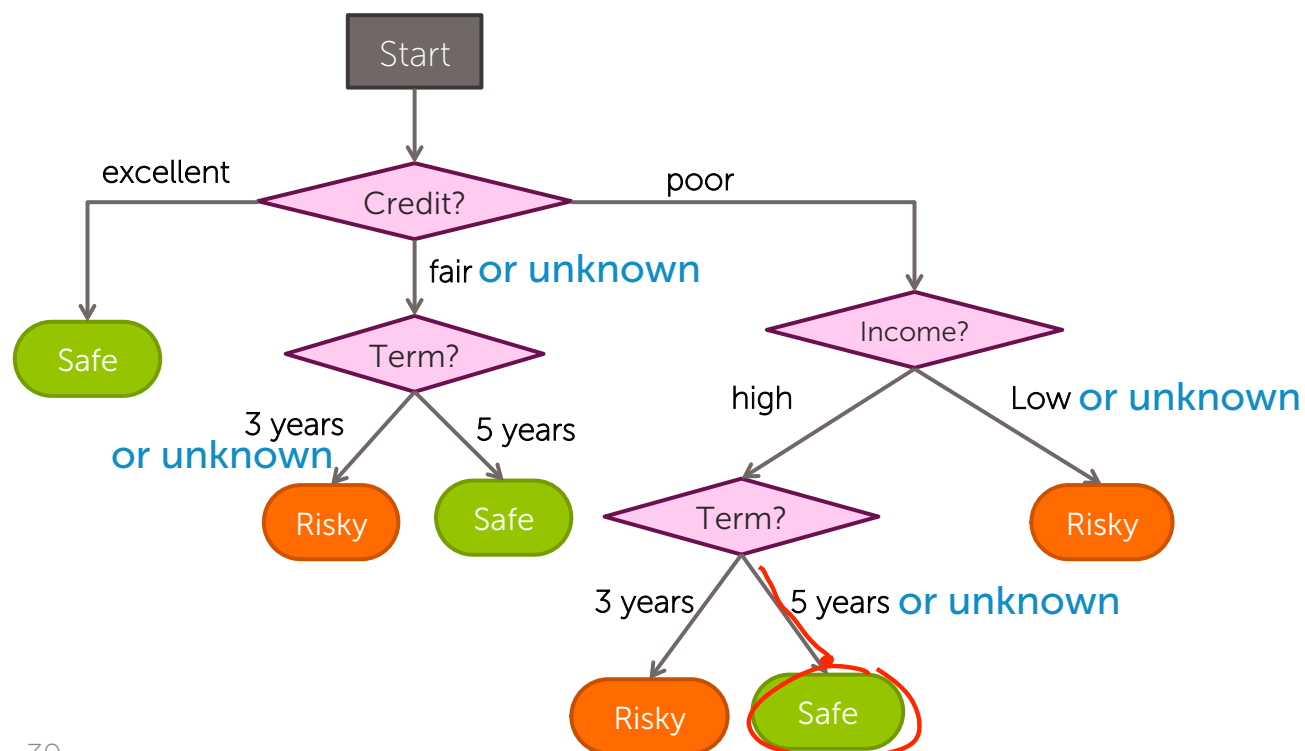

Prediction with missing values becomes simple

$\mathbf{x}_i = (\text{Credit} = ?, \text{Income} = \text{high}, \text{Term} = 5 \text{ years})$

Prediction with missing values becomes simple

$\mathbf{x}_i = (\text{Credit} = \text{poor}, \text{Income} = \text{high}, \text{Term} = ?)$

Explicitly handling missing data by learning algorithm: Pros and Cons

Pros

- Addresses training and prediction time
- **More accurate predictions**

Cons

- Requires modification of learning algorithm
 - Very simple for decision trees

Feature split selection with missing data

Greedy decision tree learning

- Step 1: Start with an empty tree
- Step 2: Select a feature to split data
- For each split of the tree:
 - Step 3: If nothing more to, make predictions
 - Step 4: Otherwise, go to Step 2 & continue (recurse) on this split

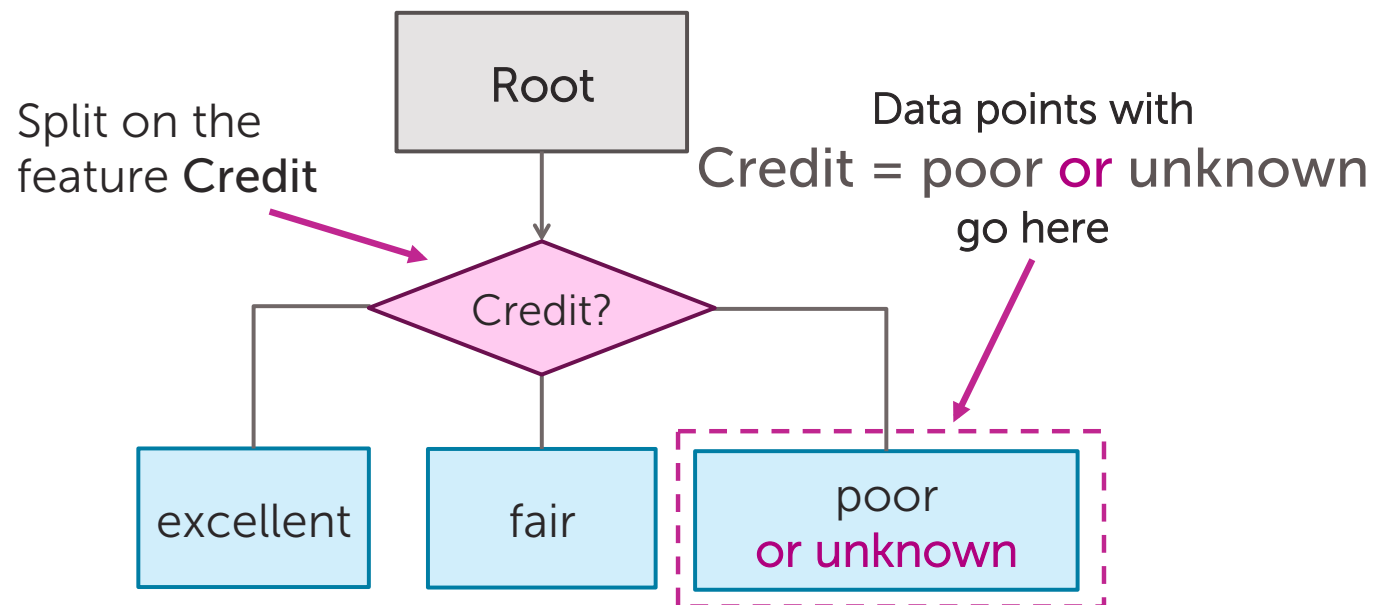

Pick feature split
leading to lowest
classification error

Must select feature &
branch for missing values!

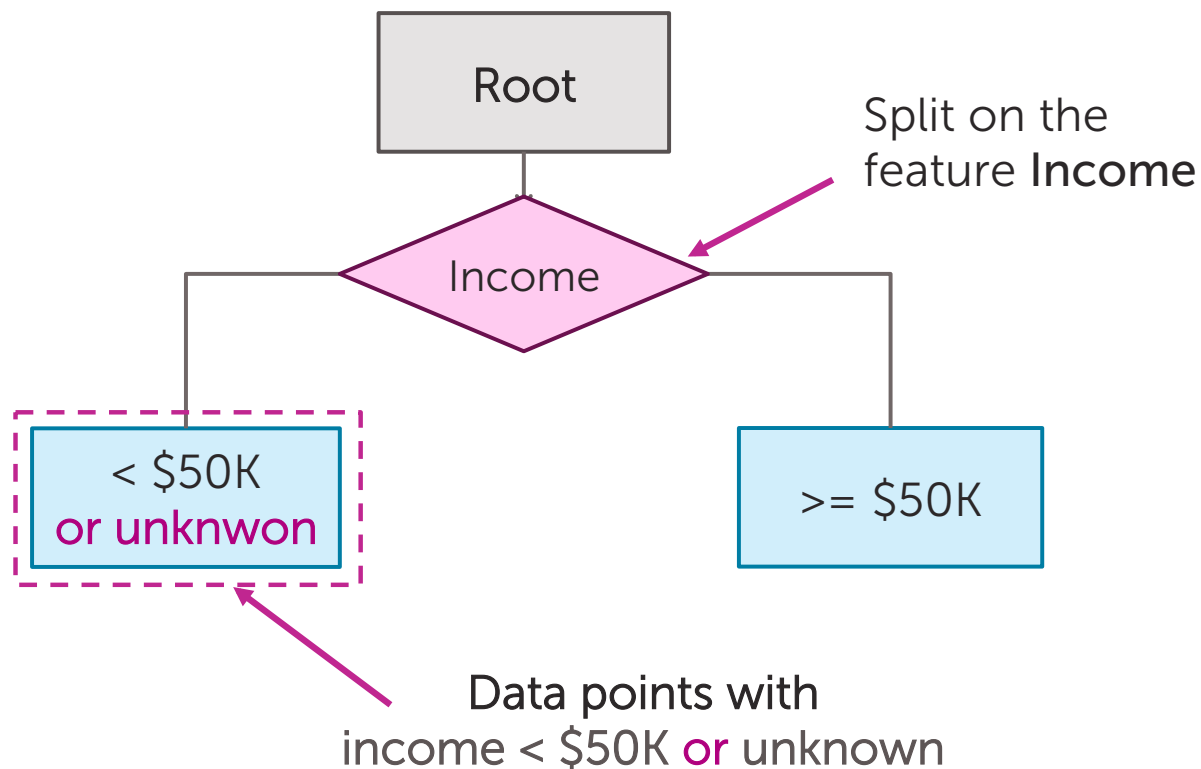

Feature split (without missing values)

Feature split (**with** missing values)

Missing value handling in threshold splits

Should **missing** go left, right, or middle?

Choose branch that leads to lowest classification error!

Choice 1: Missing values go with Credit=excellent

Choice 2: Missing values go with Credit=fair

Choice 3: Missing values go with Credit=poor

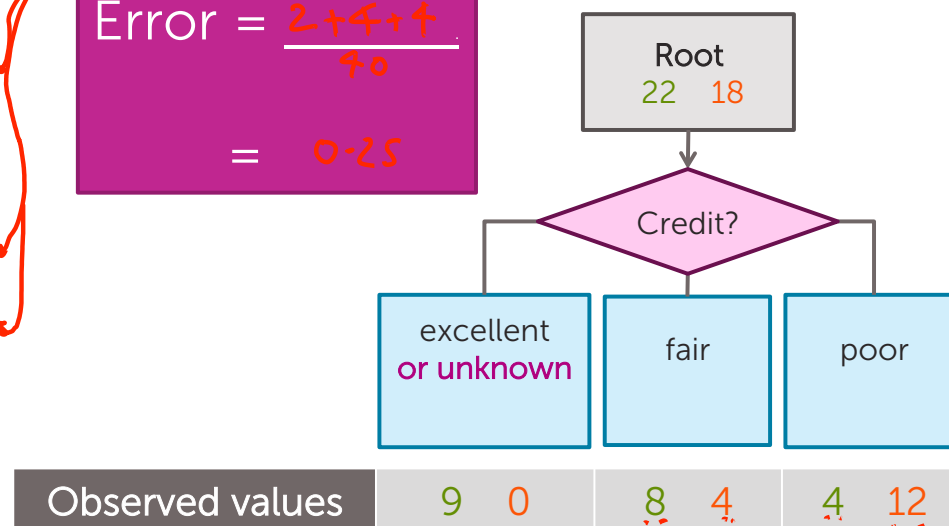

Computing classification error of decision stump with missing data

N = 40, 3 features

Credit	Term	Income	y
excellent	3 yrs	high	safe
?	5 yrs	low	<u>risky</u>
fair	3 yrs	high	safe
poor	5 yrs	high	risky
?	3 yrs	low	<u>risky</u>
?	5 yrs	low	<u>safe</u>
poor	3 yrs	high	risky
poor	5 yrs	low	safe
fair	3 yrs	high	safe
...

$$\text{Error} = \frac{2+4+4}{40} = 0.25$$

0 0 0

Use classification error to decide

Best choice \rightarrow assign "unknown"
to Credit = poor

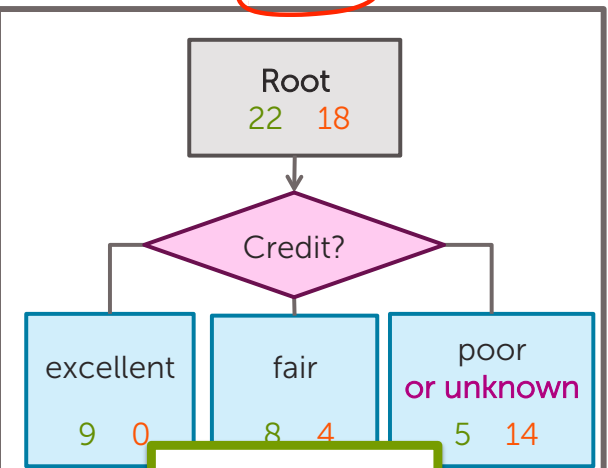

Choice 1: error = 0.25

Choice 2: error = 0.25

Choice 3: error = 0.225

WINNER

Feature split selection algorithm with missing value handling

- Given a subset of data M (a node in a tree)
- For each feature $h_i(x)$:
 1. Split data points of M where $h_i(x)$ is *not* “unknown” according to feature $h_i(x)$
 2. Consider assigning data points with “unknown” value for $h_i(x)$ to each branch
 - A. Compute classification error split & branch assignment of “unknown” values
- Chose feature $h^*(x)$ & branch assignment of “unknown” with lowest classification error

Summary of handling missing data

What you can do now...

Describe common ways to handling missing data:

1. Skip all rows with any missing values
2. Skip features with many missing values
3. Impute missing values using other data points

Modify learning algorithm (**decision trees**) to handle missing data:

1. Missing values get added to one branch of split
2. Use classification error to determine where missing values go
